

How can optical modules replace transceivers

Overview

These transceiver modules are engineered for hot swapping, which means that the transceivers can insert or be removed from their network ports without interrupting operation or powering down the network equipment. This allows for easy maintenance, upgrades, and installation. As an essential component of optical fiber communication, optical modules are optoelectronic devices that facilitate the conversion between optical and electrical signals during the transmission process. Understanding their application is key to building robust, future-proof 5G networks. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside. This article unpacks the technologies powering this leap (silicon photonics, advanced modulation, and co-packaged optics), compares deployment paradigms, and delivers a tactical upgrade roadmap that balances performance, cost, and scalability. This article will explore the evolution of modules' speed and form factor from 400G to 1.
