

# What is the function of a relay protection CT

## Overview

A CT converts large primary currents to standardized secondary currents (commonly 1 A or 5 A) while providing galvanic isolation. REF Protection Definition: REF protection is a scheme used in transformers to detect internal earth faults by monitoring unbalanced currents in the transformer phases and neutral. External Fault Current Flow: During an external fault, balanced currents in the line CT and neutral CT result in zero. This integration of protection, CT supervision and associated timers makes it easy to simplify system design and secondary wiring. Three fundamental components required for each circuit breaker. CT's transform line current down to a signal level that is. The CTs (current transformers) and VTs (voltage transformers) are provided in the plants to reduce the voltage and current values of the plant to values such as to be able to be detected by measurement and protection devices. Its main purpose is to safeguard electrical equipment like transformers, generators, and transmission lines from damage due to. What is the principal working of current transformer supervision protection function in VAMP 255/245/230 relay's. The device supervise the external wiring between the device terminals and current transformers (CT) and the CT them selves.
